Exam Feedback

EE4-05: Traffic Theory &Queueing Systems

Q1 part a) this question was successfully answered by most students and the average for the cohort was close to full mark. In part b) all the students attempted the answer but with uneven success. The mean and variance of the model was introduced in lectures, but its derivation was not elaborated.

Q2) This question was attempted and successfully answered by most students. This is expected as the subjects being asked in this question (parts a and b) are extension of various course syllabus parts.

Q3 part a) question challenge the students on an application problem. In terms of the derivation of that model the challenge was to jointly estimate model parameters using two alternative approaches. Not many student accurately answered this question. In part b), even though the actual expression is part of normal discussions during lecture time, the derivation requires physical interpretation and understating of the M/M/K queueing system. Most student attempted and answer to this question with different level of success.

Q4 part a) students attempted the question but the quality of answers differ in their ability to identify the proper state space and the structure of the underlying model. In part b) the derivation requires some basic knowledge and one approximation (which was included in the question as a hint). The student that attempted this question successfully answered it.

Overall the exam marks are as expected and averages follow historical trends. There was not a single question or part of it that was not attempted by a number of students. The exam is structured in a way that has been consistent in terms of its mapping to different parts of the course and to its historical setting.
